Soft Computing

# Smaller Network: RNN

This is our fully connected network. If  $x_1 \dots x_n$ ,  $n$  is very large and growing, this network would become too large. We now will input **one  $x_i$  at a time**, and **re-use the same edge weights**.

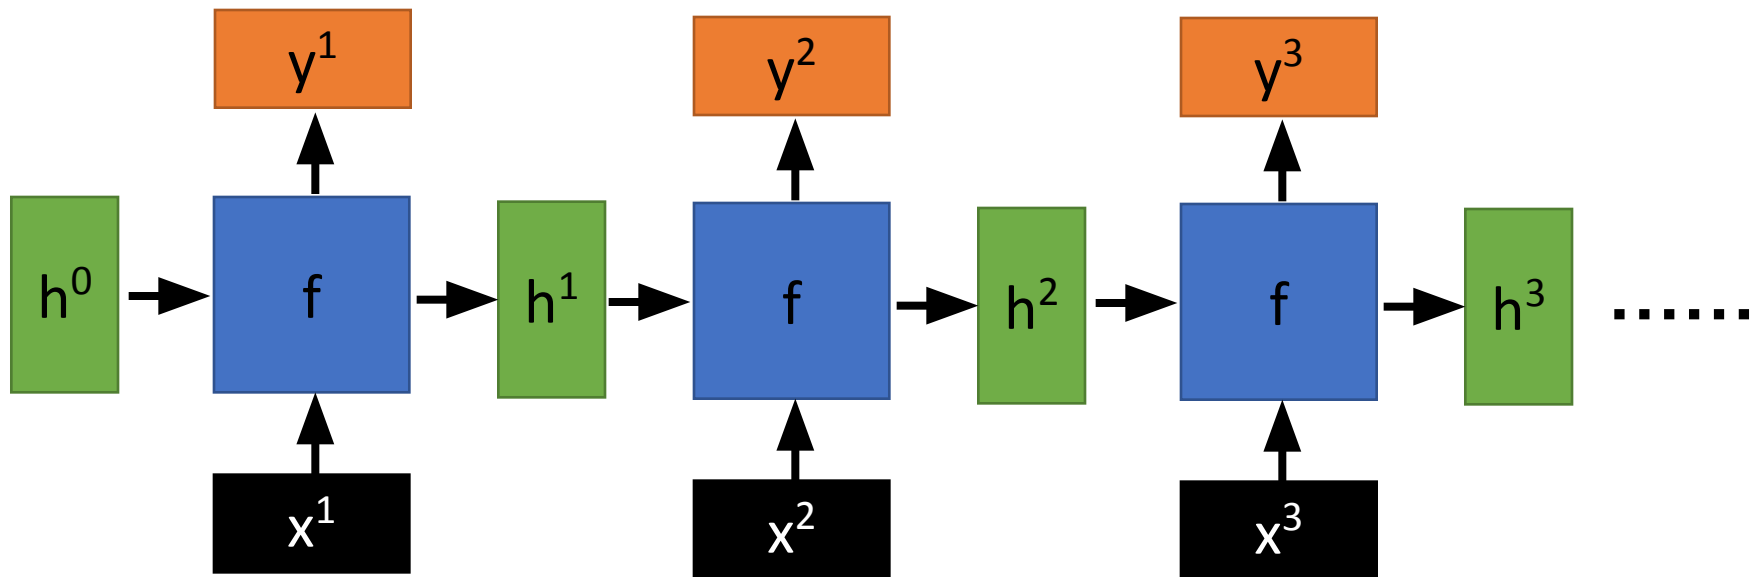

# Recurrent Neural Network

# How does RNN reduce complexity?

- Given function  $f: h', y = f(h, x)$

$h$  and  $h'$  are vectors with the same dimension

No matter how long the input/output sequence is, we only need one function  $f$ . If  $f$ 's are different, then it becomes a feedforward NN. This may be treated as another compression from fully connected network.

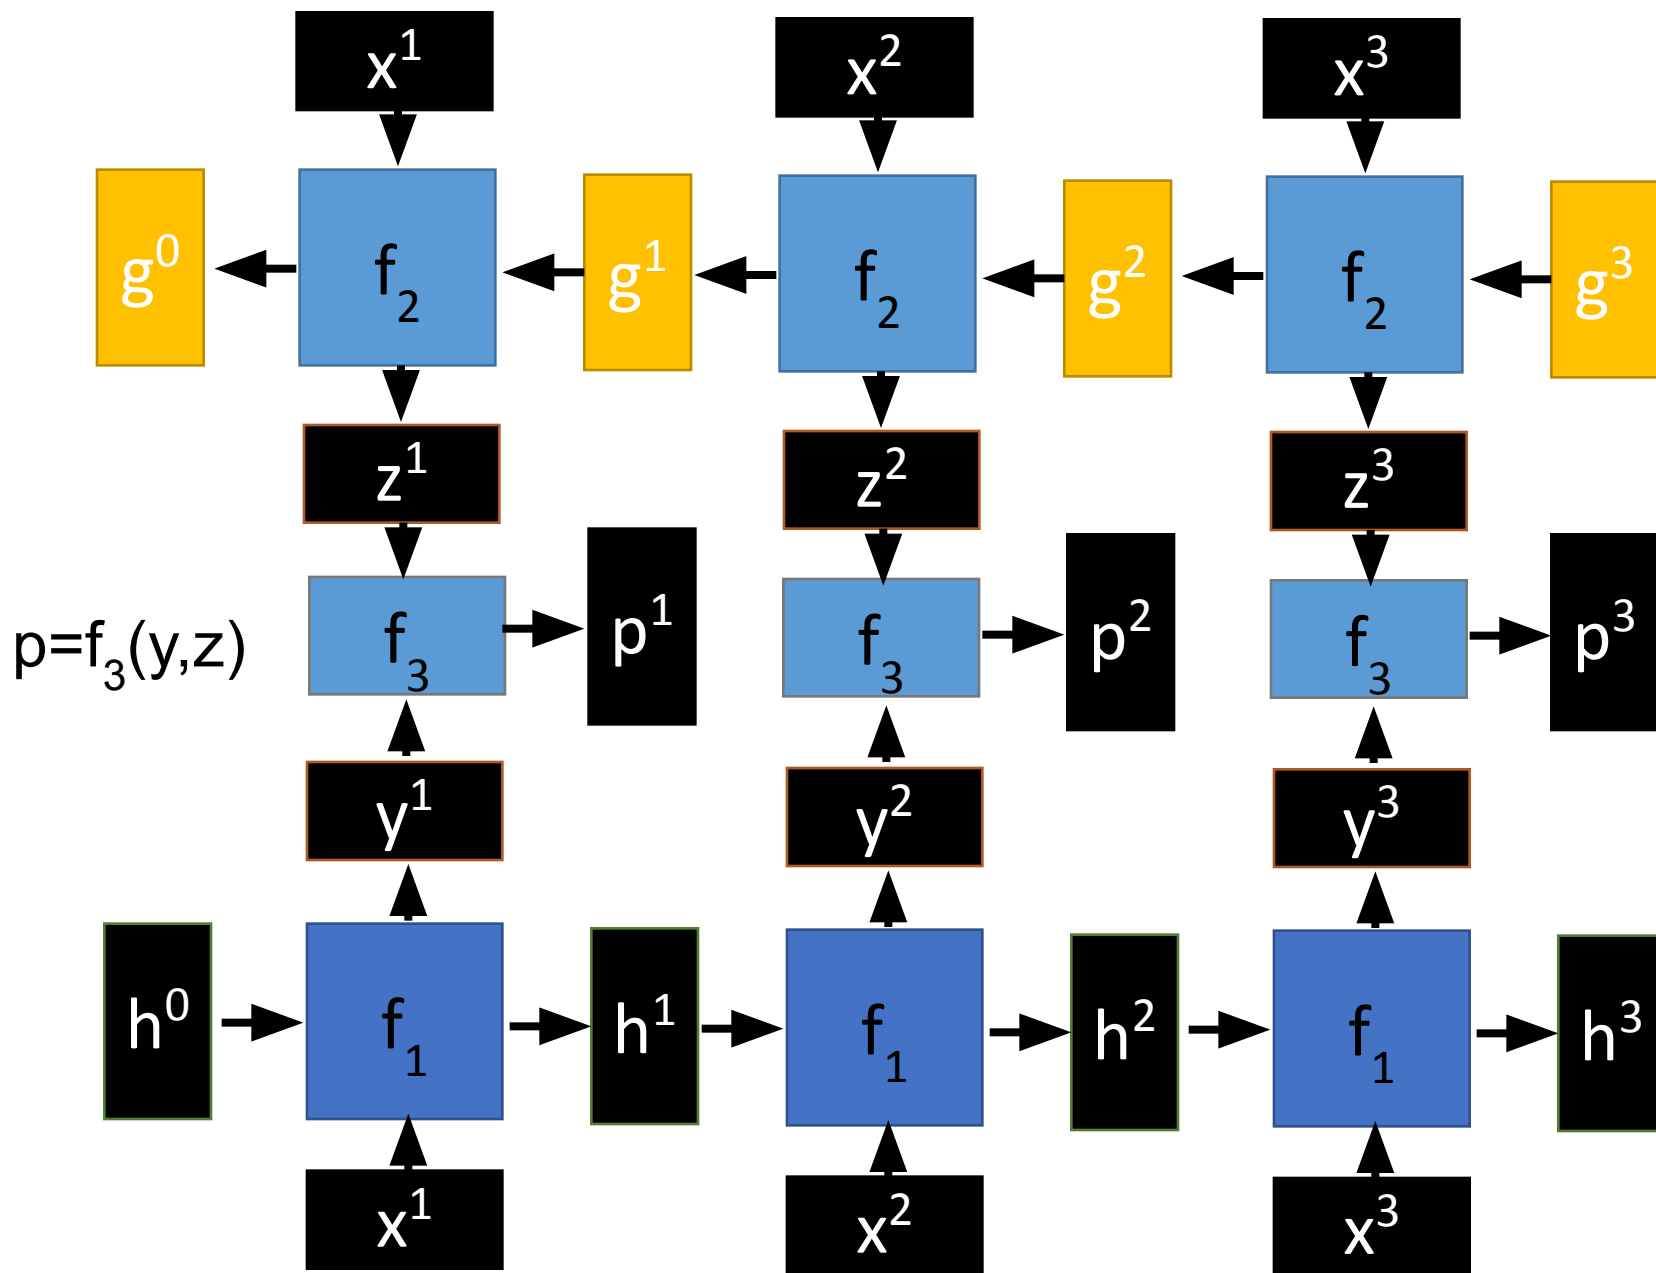

# Deep RNN

$$h', y = f_1(h, x), \quad g', z = f_2(g, y) \quad \dots$$

# Bidirectional RNN

$$y, h = f_1(x, h) \quad z, g = f_2(g, x)$$

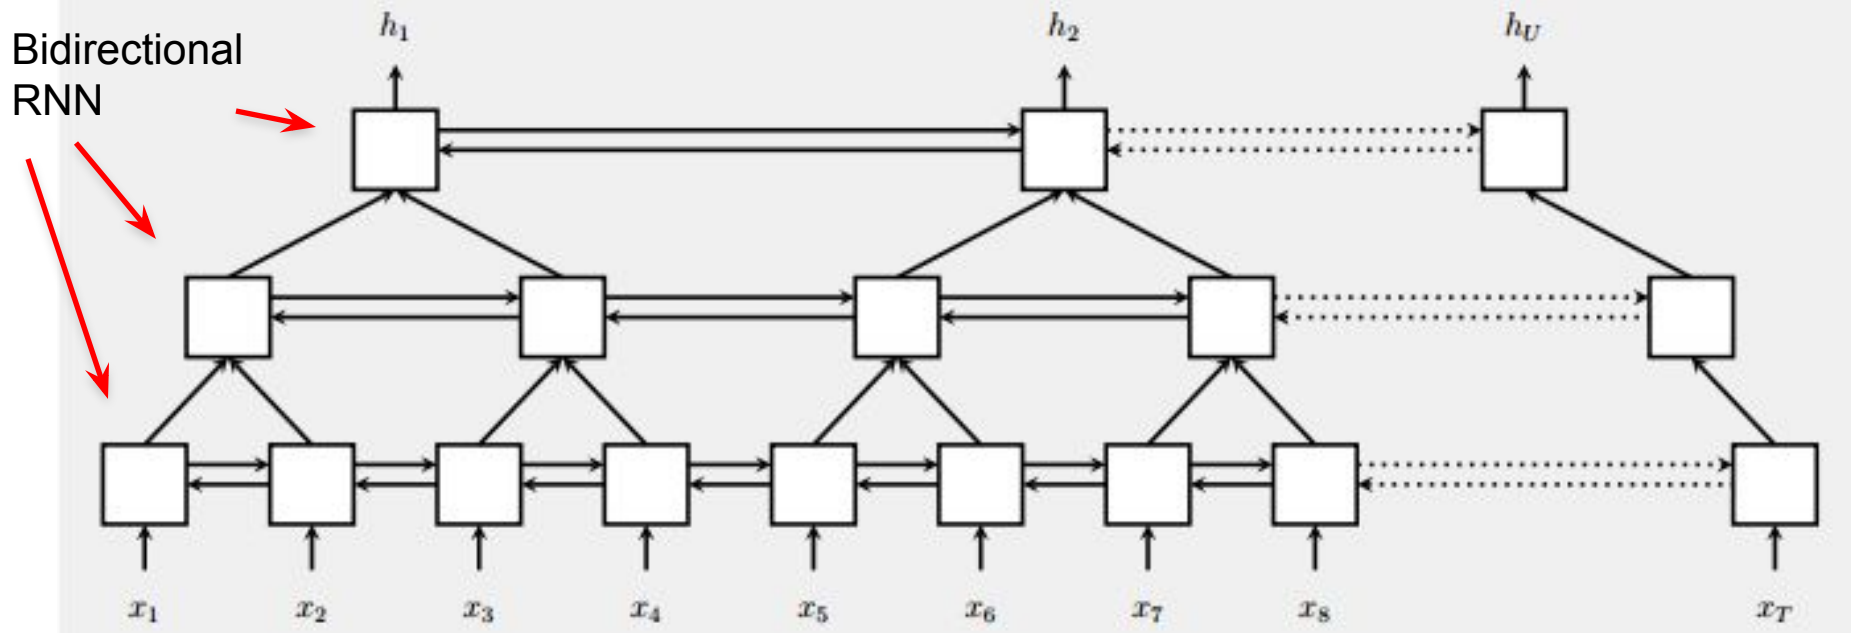

# Pyramid RNN

Significantly speed up training

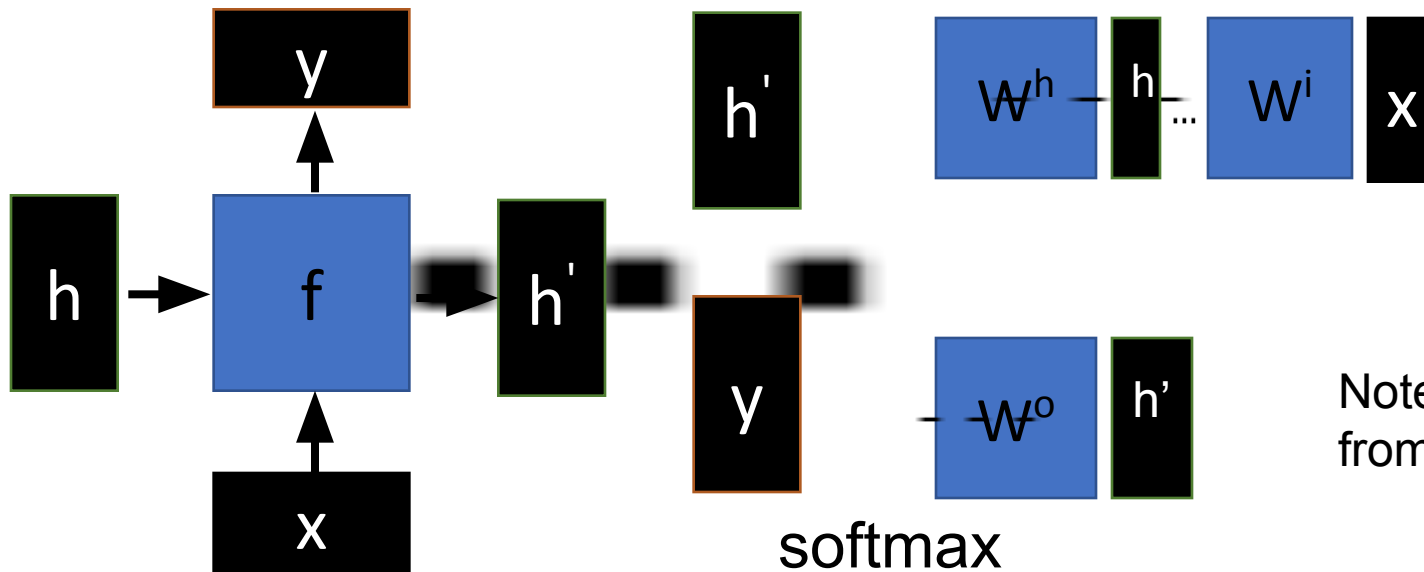

- Reducing the number of time steps

W. Chan, N. Jaitly, Q. Le and O. Vinyals, “Listen, attend and spell: A neural network for large vocabulary conversational speech recognition,” ICASSP, 2016

# Naïve RNN

- 

We have ignored the bias

# Naïve RNN

# Problems with naive RNN

- When dealing with a time series, it tends to forget old information. When there is a distant relationship of unknown length, we wish to have a “memory” to it.
- Vanishing gradient problem.

The sigmoid layer outputs numbers between 0-1 determine how much each component should be let through. Pink X gate is point-wise multiplication.

# LSTM

Output gate  
This sigmoid gate  
controls what info  
is to be added to the cell state  
Is to decide what much  
information goes thru

Forget input  
gate gate

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t$$

The core idea is this cell  
state  $C$ : it is changed  
slowly, with only minor  
Vanishing gradient problem in  
linear interactions. It is very  
easy for information to flow  
along it unchanged.  
Why sigmoid or tanh?  
Sigmoid: 0, 1 gating as switch.  
ReLU replaces tanh ok?

# LSTM

- Sigmoid specifically, is used as the gating function for the three gates (in, out, and forget) in LSTM, since it outputs a value between 0 and 1, and it can either let no flow or complete flow of information throughout the gates.
- On the other hand, to overcome the vanishing gradient problem, we need a function whose second derivative can sustain for a long range before going to zero. Tanh is a good function with the above property.
- A good neuron unit should be bounded, easily differentiable, monotonic (good for convex optimization) and easy to handle. If you consider these qualities, then you can use ReLU in place of the tanh function since they are very good alternatives of each other.
- But before making a choice for activation functions, you must know what the advantages and disadvantages of your choice over others are.

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f)$$

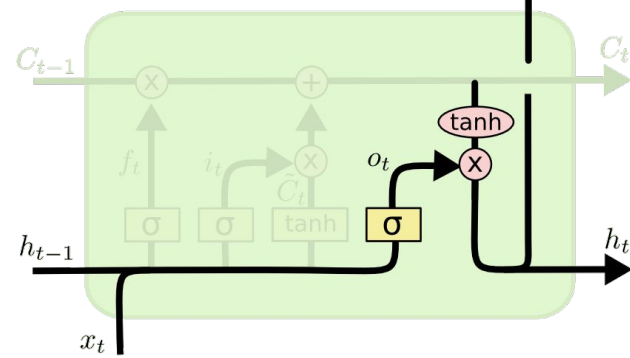

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i)$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C)$$

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t$$

$$o_t = \sigma(W_o [h_{t-1}, x_t] + b_o)$$

$$h_t = o_t * \tanh(C_t)$$

$i_t$  decides what component is to be updated.

$C'_t$  provides change contents

Updating the cell state

Decide what part of the cell state to output

# RNN vs LSTM

(a) RNN

(b) LSTM

# Peephole LSTM

Allows “**peeping** into the memory”

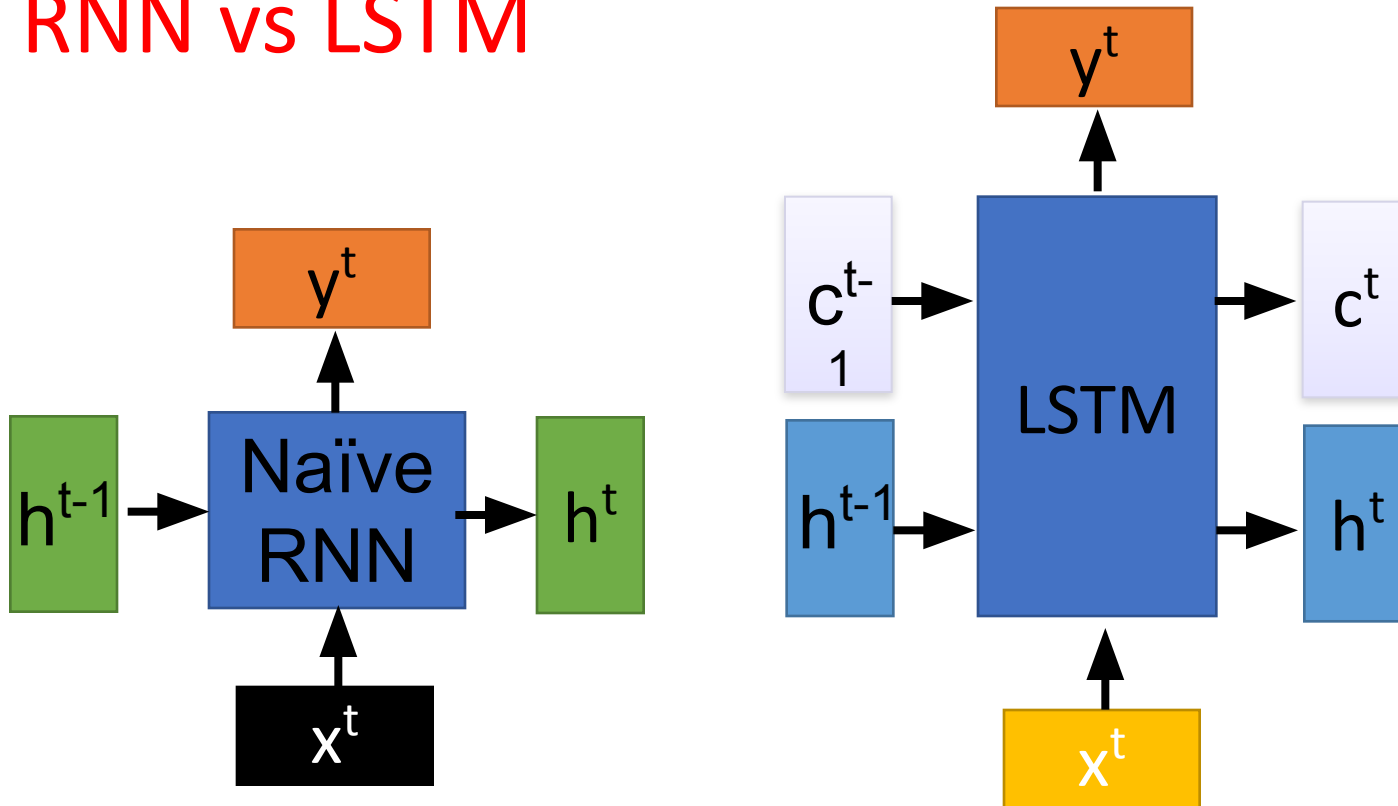

$$f_t = \sigma(W_f \cdot [C_{t-1}, h_{t-1}, x_t] + b_f)$$

$$i_t = \sigma(W_i \cdot [C_{t-1}, h_{t-1}, x_t] + b_i)$$

$$o_t = \sigma(W_o \cdot [C_t, h_{t-1}, x_t] + b_o)$$

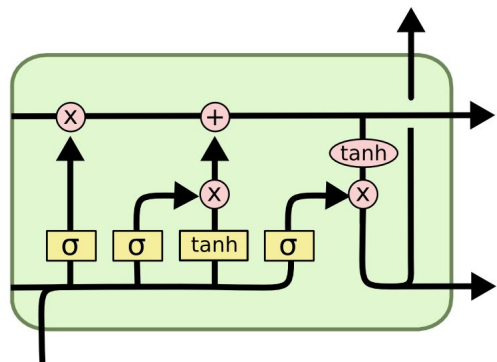

# Naïve RNN vs LSTM

$c$  changes slowly  $\longrightarrow c^t$  is  $c^{t-1}$  added by something

$h$  changes faster  $\longrightarrow h^t$  and  $h^{t-1}$  can be very different

These 4 matrix computation should be done concurrently.

$c^{t-1}$

Controls forget gate      Controls input gate      Updating information      Controls Output gate

**Information flow of LSTM**

$$z = \tanh(W \begin{bmatrix} h^{t-1} \\ c^{t-1} \end{bmatrix})$$

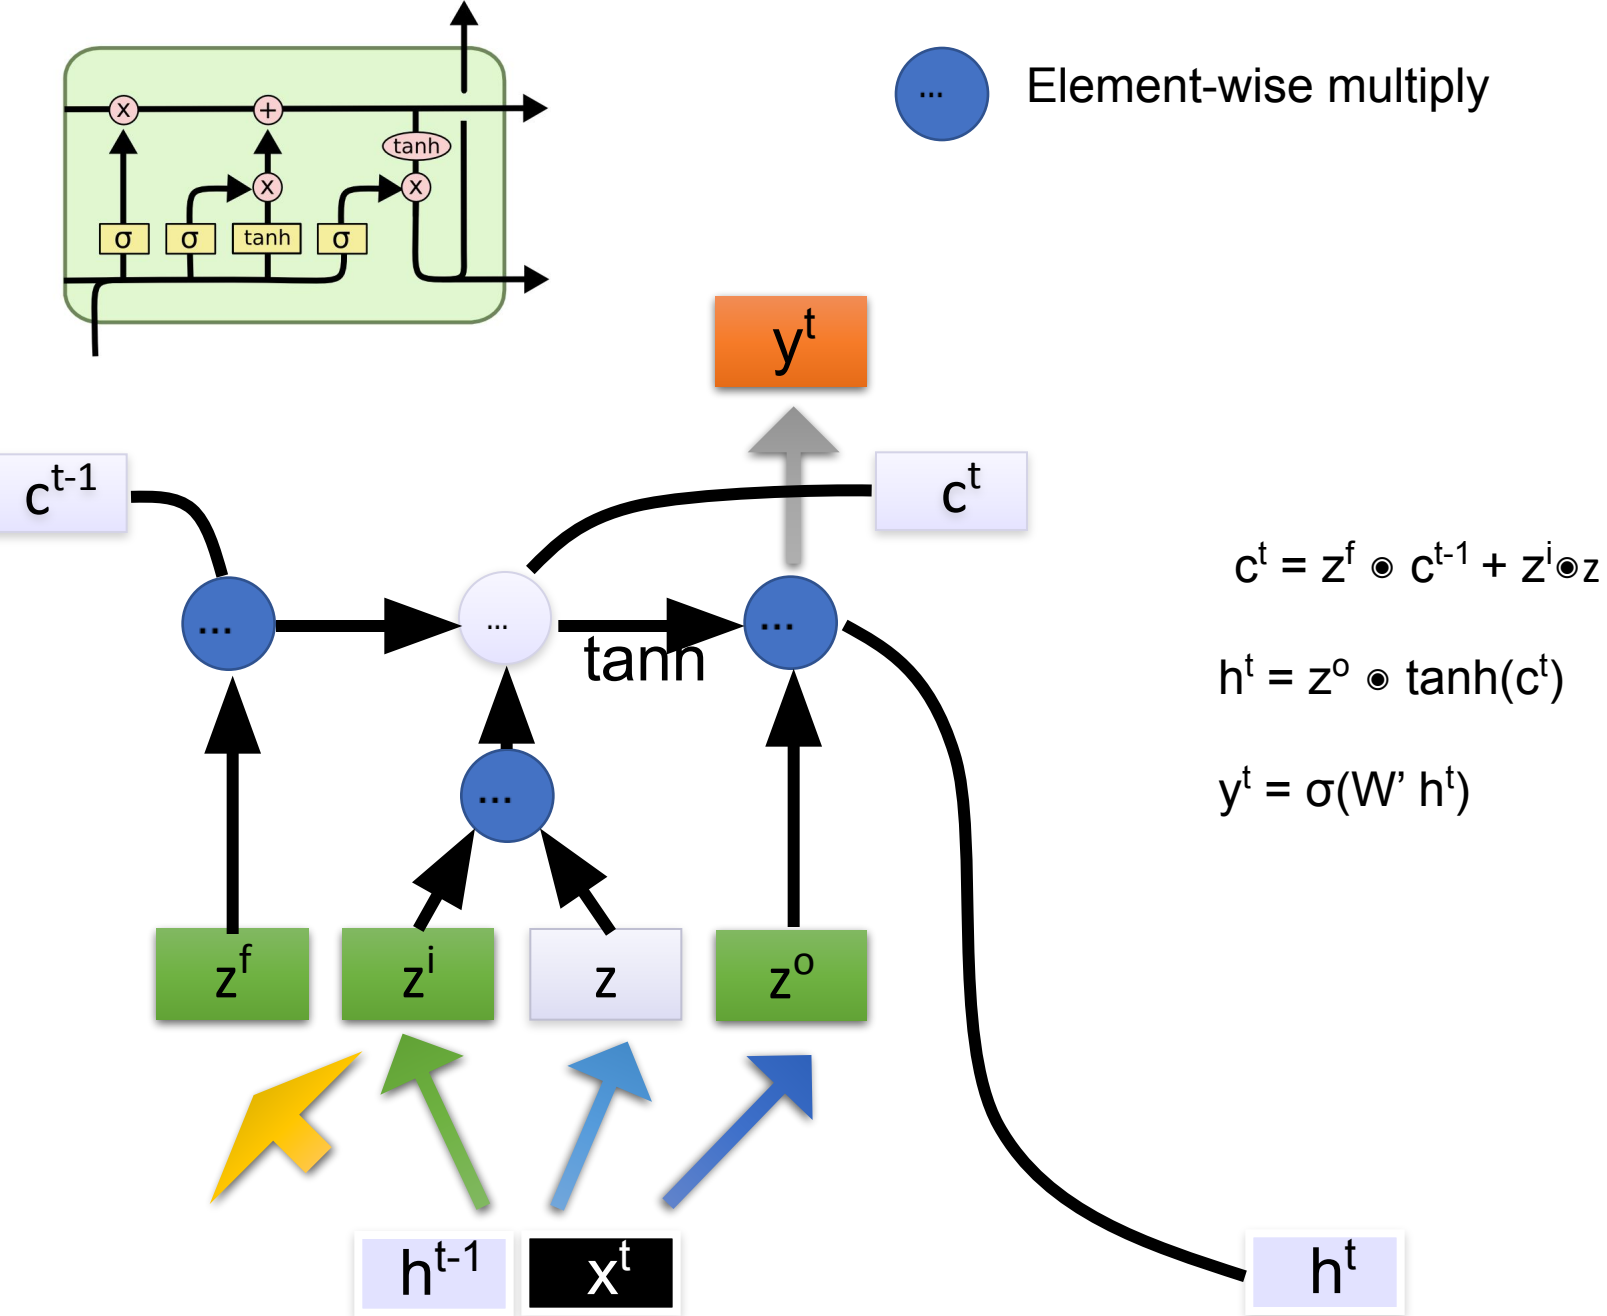

↑  
diagonal

$z^o$   $z^f$   $z^i$  obtained by the same way

“peephole”

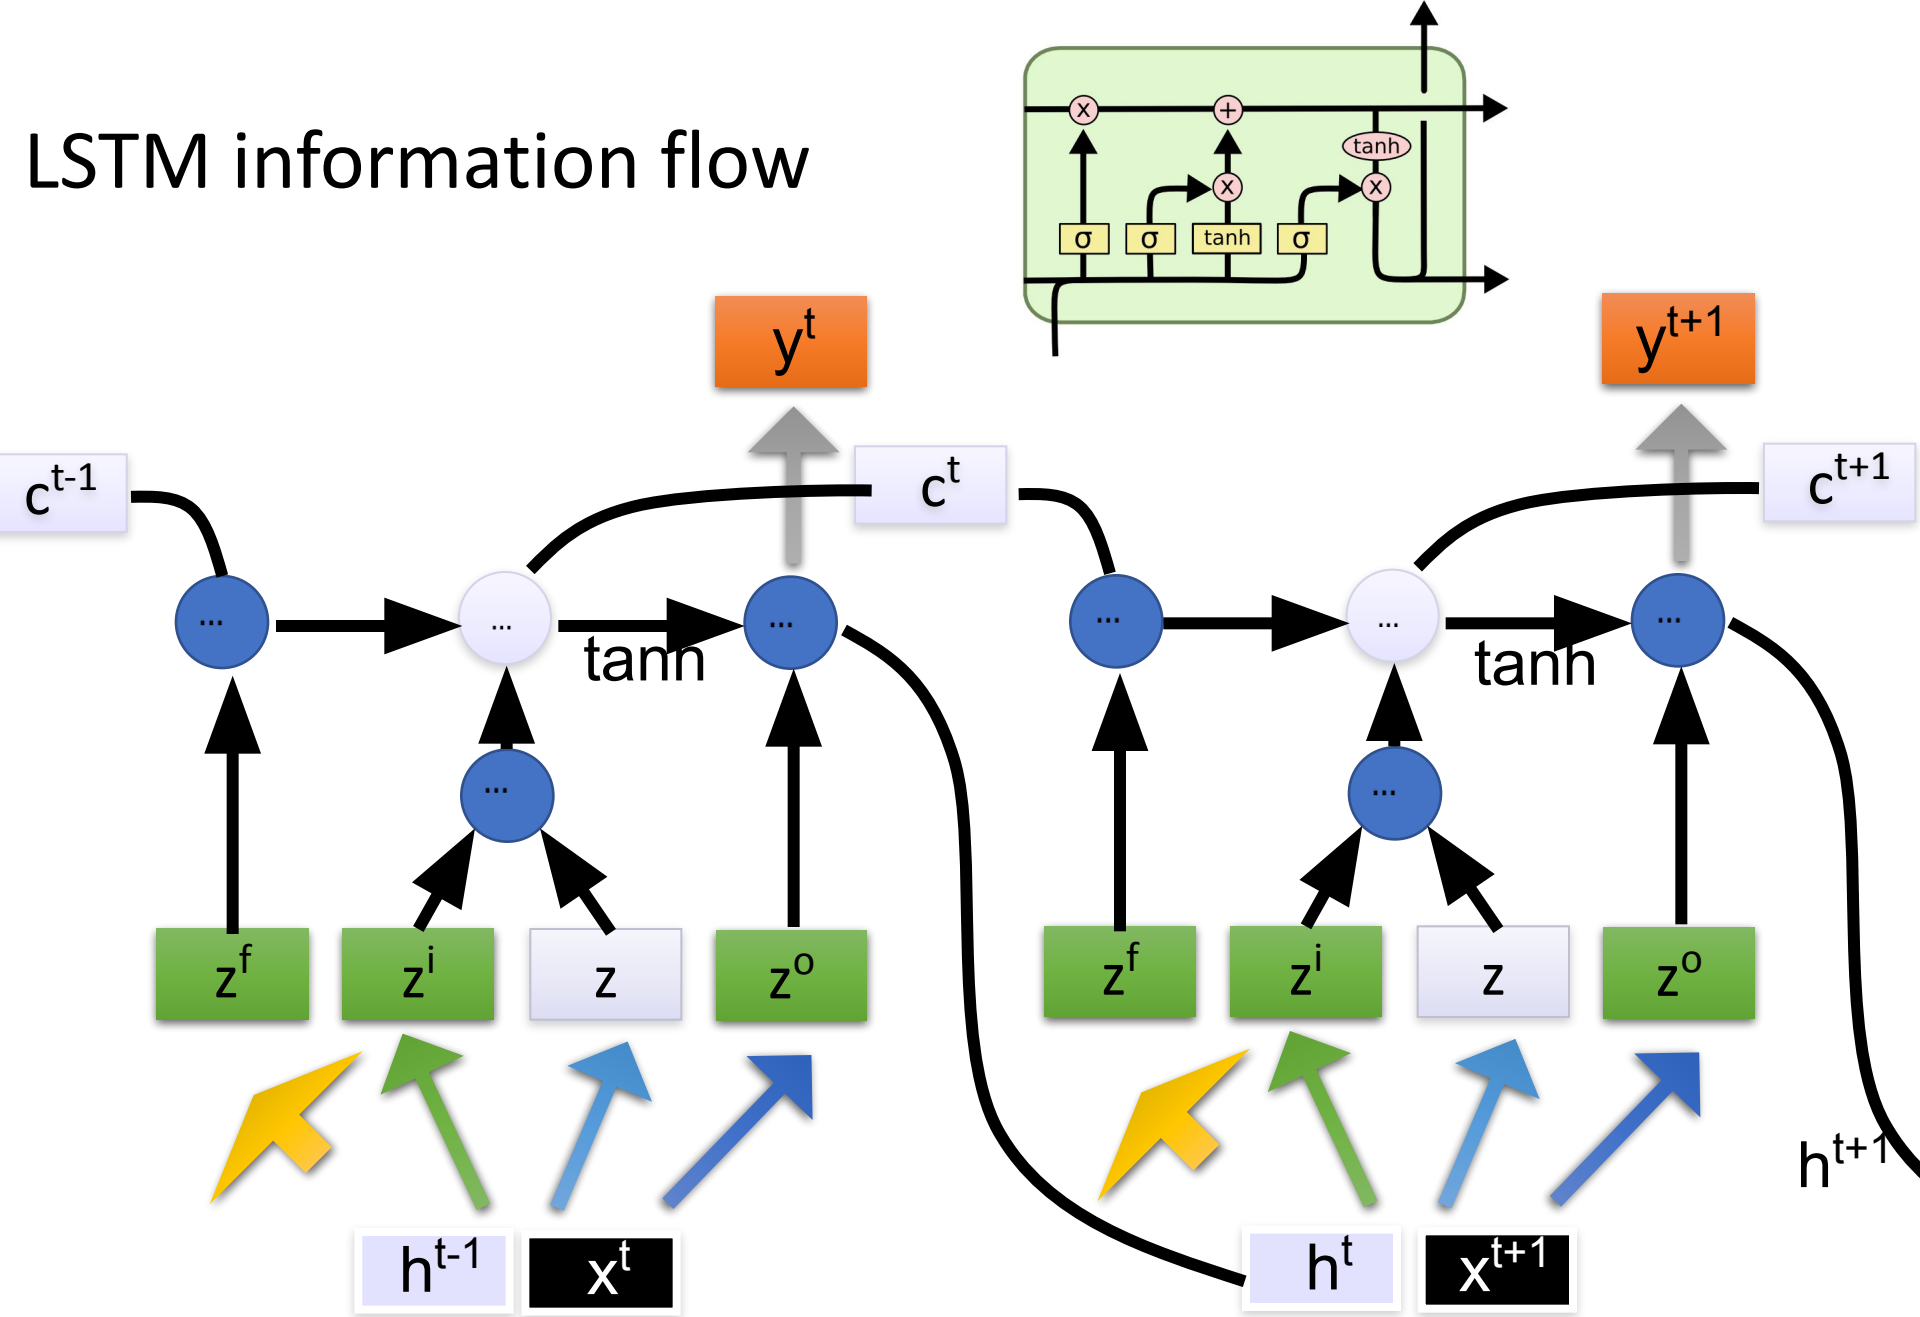

**Information flow of LSTM**

**Information flow of LSTM**

# LSTM information flow

Information flow of LSTM

# GRU – gated recurrent unit

(more compression)

$$z_t = \sigma(W_z \cdot [h_{t-1}, x_t])$$

$$r_t = \sigma(W_r \cdot [h_{t-1}, x_t])$$

$$\tilde{h}_t = \tanh(W \cdot [r_t * h_{t-1}, x_t])$$

$$h_t = (1 - z_t) * h_{t-1} + z_t * \tilde{h}_t$$

It combines the **forget** and **input** into a single **update gate**. It also merges the cell state and hidden state. This is simpler than LSTM. There are many other variants too.

$X, *$ : element-wise multiply

# LSTM and GRU

- LSTM [Hochreiter&Schmidhuber97]

- GRU [Cho+14]

GRUs also take  $x_t$  and  $h_{t-1}$  as inputs. They perform some calculations and then pass along  $h_t$ . What makes them different from LSTMs is that GRUs don't need the cell layer to pass values along. The calculations within each iteration ensure that the  $h_t$  values being passed along either retain a high amount of old information or are jump-started with a high amount of new information.

# Feed-forward vs Recurrent Network

1. Feedforward network does not have input at each step
2. Feedforward network has different parameters for each layer

$$a^t = f_t(a^{t-1}) = \sigma(W^t a^{t-1} + b^t)$$

t is layer

$$a^t = f(a^{t-1}, x^t) = \sigma(W^h a^{t-1} + W^i x^t + b^i)$$

t is time step

We will turn the recurrent network 90 degrees.
